Final Project ME239, Winter 2011

Polizzi, DeVecchio, Sorrentino

ME239 FINAL PROJECT  
 Nicole Polizzi<sup>1</sup>, Paul DeVecchio<sup>2</sup>, and Mike Sorrentino<sup>3</sup>  
 Department of Mechanical Engineering, Stanford University  
 Stanford, California

**Abstract.** The abstract should summarize what you did and what you learned quantitatively. Summarize the important results for easy reference. Don't just write something along the lines of "This paper describes the design of X, outlines the fabrication and testing methods, and analyzes expected performance." Instead be specific about the main features of the design, results of your analysis, and summarize key features of how you would make and test it. The summary should be substantive but generally should not include figures or references. Your paper should summarize expected device performance quantitatively, describe methods, materials, challenges of your design. Formatting and content descriptions are provided here.

**Background.** In this section, discuss what you set out to do, your design requirements, and compare and contrast to prior work.

The Annual Poster Sessions for Stanford University's E240, Introduction to Micro and Nano Electromechanical Systems (M/NEMS), will be held on December 3 and 5, 2008, from 2:15 to 3:45 pm on the steps of the Durand building on Stanford University Campus. Papers for each project should be submitted electronically as PDF files by 5pm Tuesday, December 2. These papers will be printed and bound into "ENGR240 Class Proceedings" and distributed at the poster sessions.

- Affiliation: 11 points, regular;
- City, State: 12 points, regular;
- Text body: 10 points, regular; paragraphs without indent
- Figure captions: 10 points, *italic*;
- Table captions: 10 points, *italic*;
- References: 10 points, regular, numbered in [ ].

**Analysis of Performance.** In this section, you should quantify the expected performance of your design and how you will test it. Justify your assumptions and compare expected performance to existing devices. Graphs, tables, figures summarizing these data will convey this information succinctly.

## THE PRIMARY CILIUM: A WELL-DESIGNED FLUID FLOW SENSOR

Bryan C. Petráš  
Department of Mechanical Engineering, Stanford University  
Stanford, California

The primary cilium is a highly specialized surface projection which extends from the apical surface of almost every vertebrate cell. After its initial discovery over 100 years ago, primary cilia were long overlooked and even regarded by some to be extraneous genetic remnants from our evolutionary past. However, in the past decade, a wealth of evidence has begun to accumulate, indicating that cilia in various cell types act not only as mechanical and chemical sensors, but also play important roles in intracellular signaling and cell division<sup>1</sup>. Some have even suggested that cilia-related dysfunction may have an important role in modern human epidemics such as obesity, hypertension and diabetes<sup>2</sup>. One such link between cilia-related dysfunction and human disease that has been explored extensively involves the role of the primary cilia of renal epithelial cells as flow sensors. It is believed that a dysfunction in these cilia results in polycystic kidney disease (PKD), the most common hereditary disease in the United States, with an estimated 800,000 current cases<sup>3</sup>. Numerous models have been proposed to explain the mechanotransduction mechanism which allows the primary cilia of renal epithelial cells to detect fluid flow, but many questions remain. Understanding the transduction mechanism and the features of the primary cilium which make it an ideal flow sensor will not only answer many interesting questions in biology and biomechanics, but could aid in the treatment of PKD and other diseases which are caused by cilia-related dysfunction.

### INTRODUCTION TO THE PRIMARY CILIUM

The primary cilium is a long, cylindrical, microtubule-based structure which extends from the apical surface of most vertebrate cells, as shown in Figure 1. In general, cells only have a single primary cilium. Referring to the structure, the main structural element of the primary cilium is a collection of nine circumferentially-arranged doublet microtubules situated by membrane continuous with the cell membrane<sup>4</sup>. These doublet microtubules extend from a structure known as a basal body within the cell, which links the base of the primary cilium to the cytoskeleton. The basal body consists of nine triplet microtubules, and two of the microtubules of each triplet form the axoneme of the primary cilium. Further structural support is provided by the transitional fibers (also doublets) which add stability to the complex via attachments to the cell membrane<sup>5</sup>. In conjunction with a terminal plate at the end of the basal body, these transitional fibers also act as a protein filter, only allowing certain proteins to enter and exit the cilium<sup>6</sup>. At the far end of the cilium, the axoneme becomes more variable, but is typically composed of nine single microtubules<sup>7</sup>. Although cilia are not isolated from the cell by a membrane, it seems reasonable to consider them to be organelles due to their unique structure; their axoneme locates past the cell periphery, and the sensitivity to protein movement across their boundaries resulting from the transitional fibers and the terminal plate.

Depending on the species, primary cilia of renal epithelial cells typically vary between 2-20  $\mu\text{m}$  in length *in vivo*<sup>8</sup>. However, lengths up to 20  $\mu\text{m}$  have been observed *in vitro*<sup>9</sup>. In addition, studies involving more renal epithelial cells measured primary cilia 2-3  $\mu\text{m}$  long and 0.2  $\mu\text{m}$  in diameter on average<sup>10</sup>. Since microtubules have an outer diameter of  $\sim 30 \text{ nm}$ , this relatively small diameter indicates that nearly half the volume of a primary cilium is occupied by the microtubules alone<sup>11</sup>.

Fig. 1. Primary cilium structure. (A) Electron micrograph of the primary cilium of a mouse brain radial glia. (B) Schematic showing structure of the basal body and primary cilium. Adapted from Ingber et al. (2006)

# downloadable grading criteria from coursework

Instructions for Judges  
according to ASME / SBC conference review guidelines

The presentation format includes the structure of the presentation and its composition. In general, a presentation should be structured to include an introduction, method, analysis, results, a conclusion, and references. The introduction should define the problem, scope of the study, and a brief background of previous work. The method section also should be brief to leave the majority of the report body for results and discussion. The final paragraph should be a brief paragraph on inference or conclusions reached.

**Technical merit** should be judged on the completeness of what is reported. For scientific studies, the result should support the conclusions presented. The key is validation of the express conclusion with results and data. Unsubstantiated conclusions or results should receive minimum points. However, not all papers represent basic research. Some papers present the design of a hardware system or a new software development. Both require the development of tests and measurement procedures to validate the product.

After the scoring is complete, please indicate a final grade. Please provide a comment in the designated area that describes why you think this presentation suitable/not suitable. These comments will be collected and provide to the students for feedback.

It is not necessary for the judge to be an expert in the field represented by the paper to evaluate its technical merit using these criteria. Subjective rating of the paper's scientific contribution is not encouraged unless there is evidence that the conclusions are incorrect. A judge should feel free to consult colleagues who are experts in the field, if you are unsure about the correctness of the conclusions. Since presentations can vary from hardware designs to software technique, or simulations and modeling to basic research, each reviewer will have to use his/her own best judgment about the technical merit of the work that is presented.

### Scoring & Evaluation System:

Please use the same scoring system as for the General Abstracts for each of the evaluation categories.

Score	Provide a ranking according to
Excellent	= 100
Very Good	= 90
Good	= 80
Marginal	= 60
Poor	= 50

### Evaluation Categories

1. Structure of presentation
2. Technical merit
3. Style of presentation

Keep in mind the judges cannot be perfect, but will try to be consistent in scoring. There are multiple judges for each paper and each judge's scores will be normalized to compensate for individual variations.

## 6. mechanotransduction

## mechanotransduction

the process of **converting physical forces into biochemical signals** and **integrating these signals into the cellular response** is referred to as mechanotransduction. to fully understand the molecular basis for mechanotransduction, we need to know how externally applied forces are transmitted into and throughout the cell. different techniques have been developed to **probe mechanotransduction** by mechanically stimulate cells to address the following questions.

**What do we study in mechanotransduction?** How do cells respond to mechanical forces? ◦ How do mechanical forces lead to biochemical and molecular responses? ◦ How can we strengthen bone? ◦ How can we grow cartilage? ◦ How can we strengthen muscle? ◦ How can we improve cardiac contractility? ◦ How can we engineer tissues for artificial organs? ◦ How can we mimic the mechanical loading environment of cells in vitro? ◦ What can we learn from mechanical stimulation of cells with precisely controlled forces?

### 6.1 mechanotransduction - motivation 9

## mechanotransduction

the process of mechanotransduction can be divided into three steps

- **mechanoreception**  
detection of the stimulus and transmission of the signal from outside the cell to its inside
- **intracellular signal transduction**  
transduction of the stimulus to location in the cell where a molecular response can be generated
- **target activation**  
activation of proteins that cause alterations in cell behavior through a variety of different mechanisms

### 6.1 mechanotransduction - motivation 11

## mechanotransduction

disease	dysfunctional cell type
deafness	hair cells in the inner ear
glaucoma, loss of vision	optical neurons
muscular dystrophy	myocytes, endothelial cells, fibroblasts
cardiomyopathy	cardiomyocytes
osteoporosis	bone cells
arteriosclerosis	endothelial cells, smooth muscle cells
immune system disorders	leukocytes
central nervous system disorders	neurons

**Table 6.1:** Typical diseases associated with defects in mechanotransduction.

### 6.1 mechanotransduction - motivation 10

## mechanotransduction pathways during skin expansion

### 6.1 mechanotransduction - example 12

## mechanotransduction pathways during skin expansion

mechanotransduction in growing skin consists of three steps

- **mechanoreception**  
detection of the stimulus, stretch beyond the physiological limit, and transmission of the signal from outside the cell to its inside
- **intracellular signal transduction**  
transduction of the stimulus to the nucleus, to the location in the cell where a molecular response can be generated
- **target activation**  
activation of proteins that cause alterations in cell behavior through increased mitotic activity and increased collagen synthesis

### 6.1 mechanotransduction - example

13

## intracellular signal transduction

- **physical transduction.** the **cytoskeleton** serves as scaffold for the transduction of mechanical into biochemical signals. strain can induce conformational changes in the cytoskeleton, which may affect binding affinities to specific molecules and activate signaling pathways
- **biochemical transduction.** signaling molecules, small intracellular mediator molecules, second messengers, and network of intracellular signaling molecules
  - **Ca<sup>2+</sup>** changes in the intracellular calcium concentration are known to regulate intracellular signaling and cytoskeletal remodeling
  - **Rho** GTPases regulates many aspects of intracellular actin dynamics, Rho proteins have been described as molecular switches and play a role in cell proliferation, apoptosis, gene expression, and multiple other common cellular functions
  - **MAPK** mitogen-associated protein kinase pathways convey information to effectors, coordinate incoming information from other signaling cascades, amplify signals, and initiate a variety of response patterns
  - **NO** nitric oxide acts as a second messenger, it is a free radical that can diffuse through the plasma membrane and affect nearby cells
  - **PI3K** phosphoinositol-3-kinase is an intracellular signaling pathway regulating apoptosis

### 6.1 mechanotransduction - example

15

## mechanoreception

### integrins

mediate attachment between a cell and the extracellular matrix, play a central role in force transmission across the cell membrane, triggering targets such as nitric oxide NO signaling, mitogen-associated protein kinases MAPK, Rho GTPases, and phosphoinositol-3-kinase PI3K

### stretch-activated ion channels

open in response to elevated membrane strains, allowing positively charged calcium ions Ca<sup>2+</sup> and other cations to enter the cell, changes in the intracellular calcium concentration regulate intracellular signaling and cytoskeletal remodeling

### growth factor receptors

bind to growth factors outside the cell, thereby turning on several receptor mediated pathways inside the cell, such as nitric oxide NO signaling and mitogen-associated protein kinases MAPK

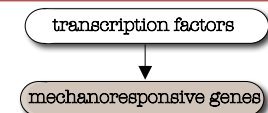

### G protein-coupled receptors

seven-transmembrane proteins, can be activated by mechanical stretch outside the cell to initiate mechanotransduction pathways inside through second messengers such as nitric oxide NO signaling and phosphoinositol-3-kinase PI3K

### 6.1 mechanotransduction - example

14

## target activation

mechanical activation initiates multiple signaling pathways, which can have a substantial overlap and crosstalk. however, since mechanically-induced signaling pathways may be shared with classical receptor-mediated pathways, they are typically difficult to study in isolation. it is clear, however, that **all these signaling pathways converge to activate transcription factors**, which **stimulate gene expression and other nuclear events**. overall, the underlying principle is that stretch invokes a cascade of events that trigger **increased mitotic activity and increased collagen synthesis**, which ultimately result in **increased skin surface area** to restore the homeostatic equilibrium state.

### 6.1 mechanotransduction - example

16

## probing mechanotransduction

in their physiological environment, cells are subjected to **various combinations of mechanical stimuli** and it is difficult to predict which stimulus is responsible for which change within the cell. in an attempt to better understand the response of the cell to individual mechanical stimuli, experiments are performed under **controlled laboratory conditions** in which different loading scenarios can be applied in a selective way. some of the classical devices that are used to **probe mechanotransduction in living cells** include the following tests.

- uniaxial and biaxial tension
- uniaxial and hydrostatic compression
- uniaxial and circumferential shear

## 6.2 probing mechanotransduction

17

## probing mechanotransduction - tension

Figure 6.1: Uniaxial and biaxial tension devices stretching cells cultured on a thin sheet.

### uniaxial tension

culture cells on a flexible thin sheet and stretch the sheet uniaxially

- advantage: relatively simple
- advantage: long sheets relatively homogeneous in loading direction
- disadvantage: lateral compression due to poisson's effect

## 6.2 probing mechanotransduction

18

## probing mechanotransduction - tension

Figure 6.1: Uniaxial and biaxial tension devices stretching cells cultured on a thin sheet.

### biaxial tension

culture cells on circular membrane and pressurize it from underneath

- advantage: ideally, all cells experience the same strain in all directions
- disadvantage: pure membrane state is difficult to achieve
- disadvantage: cell membrane needs to slide along frictionless support

## 6.2 probing mechanotransduction

19

## probing mechanotransduction - compression

Figure 6.2: Hydrostatic and uniaxial compression devices compressing plain cells and cells in a matrix.

### hydrostatic compression

culture cells in media and increase gas pressure in culture system

- advantage: ideally, all cells experience similar hydrostatic compression
- disadvantage: changes in gas composition affect chemical environment
- disadvantage: might affect cytoplasm rather than mechanoreceptors

## 6.2 probing mechanotransduction

20

## probing mechanotransduction - compression

Figure 6.2: Hydrostatic and uniaxial compression devices compressing plain cells and cells in a matrix.

### uniaxial compression

culture cells in 3d matrix and subject cell matrix to compressive loading

- advantage: mimics response of cells in their in vivo environment
- disadvantage: difficult to back out stress state of individual cells
- disadvantage: influence of poisson effect, matrix viscosity, fluid flow

## 6.2 probing mechanotransduction

21

## probing mechanotransduction - shear

Figure 6.3: Circumferential and uniaxial flow devices applying shear stress to the cell culture.

### circumferential flow

culture cells on flat plate and expose them to fluid flow by rotating disk

- advantage: single cells can be tested in fluidic environment
- disadvantage: rotational device generates inhomogeneous flow profile
- advantage: different shear profiles can be tested in one experiment

## 6.2 probing mechanotransduction

22

## probing mechanotransduction - shear

Figure 6.3: Circumferential and uniaxial flow devices applying shear stress to the cell culture.

### uniaxial flow

culture cells on substrate and expose them to laminar flow field

- advantage: single cells can be tested in fluidic environment
- advantage: flow chambers can be studied under a microscope
- disadvantage: fully developed laminar flow might be non-physiological

## the father of electrophysiology - luigi galvani

the legend of bioelectricity states that galvani dissected a frog at a table where he had been conducting experiments with static electricity. galvani's assistant touched an exposed sciatic nerve of the frog with a metal scalpel, which had picked up a charge. at that moment, they saw sparks and the dead frog's leg kick as if in life. galvani the first scientist to report the interaction between electricity and biology.  
 luigi galvani, italian anatomist, [1737-1798]

## 6.3 electrophysiology

## the cell membrane

all cellular components are contained within a cell membrane which is **extremely thin**, approximately 4-5nm, and **very flexible**. inside the cell membrane, most cells behave like a liquid as they consist of more than 50% of water. the cell membrane is **semi-permeable** allowing for a controlled exchange between intracellular and extracellular components and information.

### mechanisms of transport through the membrane

- **passive** transport driven by gradients in concentration
- **active** transport that does require extra energy; it is regulated by ion channels, pumps, transporters, exchangers and receptors

## 6.3 electrophysiology

## the cell membrane

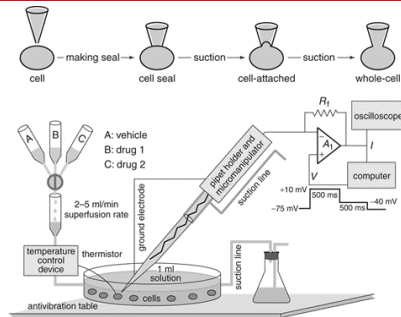

the cell membrane contains water-filled pores with diameters of about 0.8nm and **protein-fined pores called channels** which allow for the **controlled passage** of specific molecules, in particular Na<sup>+</sup>, K<sup>+</sup>, and Cl<sup>-</sup>. the phospholipid bilayer acts as a barrier to the free flow of these ions maintaining a well-regulated **concentration difference** across the cell membrane which is referred to as **membrane potential**. this implies that the membrane can selectively separate charge.

$$\phi = \phi^{\text{int}} - \phi^{\text{ext}} \quad \dots \text{ membrane potential}$$

virtually all cells are **negatively charged**, i.e., their membrane potential is negative. but how can we measure membrane charge?

## 6.3 electrophysiology

## patch clamp

the experiment that allows the study of single or multiple ion channels is called **patch clamp**. it uses a glass **micropipette** to measure the membrane potential. the pipette can have a tip diameter of only 1  $\mu\text{m}$  enclosing a membrane surface area or patch that contains one or just a few ion channels.

## 6.3 electrophysiology

29

## patch clamp

depending on the goal of the study, several variations of **patch clamp** technique can be applied. in **inside-out** and **outside-out** techniques the patch is removed from the main cell body. inside-out, outside-out, and **cell attached** techniques can be used to study the behavior of individual channels whereas **whole-cell clamp** is used to study the behavior of the entire cell.

## 6.3 electrophysiology

30

## membrane potential

	$\text{Na}^+_{\text{int}}$ mM	$\text{Na}^+_{\text{ext}}$ mM	$\text{K}^+_{\text{int}}$ mM	$\text{K}^+_{\text{ext}}$ mM	$\text{Cl}^-_{\text{int}}$ mM	$\text{Cl}^-_{\text{ext}}$ mM	resting pot. mV
nerve cell	50	437	397	20	40	556	$\phi = -65$

**Table 6.2:** Typical values for intracellular and extracellular concentrations of sodium ( $\text{Na}^+$ ), potassium ( $\text{K}^+$ ), and chloride ( $\text{Cl}^-$ ) ions.

- why is there a potential difference across the cell membrane?
- what are the mechanisms that are responsible for generating, maintaining, and regulating membrane potentials?

## 6.3 electrophysiology

31

## membrane potential

**Figure 6.4:** The fast sodium channel has two gates, an activation gate (m-gate) shown at the top and an inactivation gate (h-gate) shown at the bottom. In the resting state (left), activation gates (m-gates) are closed and inactivation gates (h-gates) are open. Rapid depolarization opens voltage-gated m-gates enabling sodium to enter the cell (second from left). Upon repolarization, inactivation gates (h-gates) close to inactivate the channel (third from left).

- **passive** discontinuous transport through **ion channels**
- **active** continuous transport through **ion pumps**

## 6.3 electrophysiology

32

## membrane potential

**Figure 6.5:** Human ventricular cardiomyocyte. In this model, the chemical state of the cardiomyocyte is characterized in terms of four ion concentrations: the free intracellular sodium, potassium, and calcium concentrations and the free calcium concentration in the sarcoplasmic reticulum. Ion concentrations are controlled through 15 ionic currents,

wong, goktepe, kuhl [2010]

## 6.3 electrophysiology

33

## membrane potential

**Figure 1.** Electrochemistry in a human ventricular cardiomyocyte. The characteristic action potential consists of five phases. Phase 0: The rapid upstroke is generated through an influx of sodium ions. Phase 1: Early, partial repolarization is initiated through the efflux of potassium ions. Phase 2: During the plateau, the net influx of calcium ions is balanced by the efflux of potassium ions. Phase 3: Final repolarization begins when the efflux of potassium ions exceeds the influx of calcium ions. Phase 4: The cell returns to its resting state.

## 6.3 electrophysiology

34

## passive transport through ion channels

**passive** transport is driven by **directed diffusion** to equilibrate concentrations. it is directed **along concentration gradients**, from high to low.

**Figure 6.5:** Passive transport through protein lined ion channel. Ion channels are specified for a particular class of ions and their pores are usually so small that only one ion can pass through it at a time.

- osmosis, transport of water through the membrane
- simple diffusion through pores and through lipid bilayer
- carrier-mediated diffusion by means of carrier molecules

## 6.3 electrophysiology

35

## passive transport through ion channels

**ion channels** are integrated membrane proteins through which ions can diffuse through the membrane. they can be either fully open or fully closed. ionic current is dependent on both **concentration gradient** and **membrane potential**.

**Figure 6.5:** Passive transport through protein lined ion channel. Ion channels are specified for a particular class of ions and their pores are usually so small that only one ion can pass through it at a time.

- voltage-gated channels
- mechanically gated channels
- ligand gated channels
- light gated channels

## 6.3 electrophysiology

36

## ion channels - mechanically gated

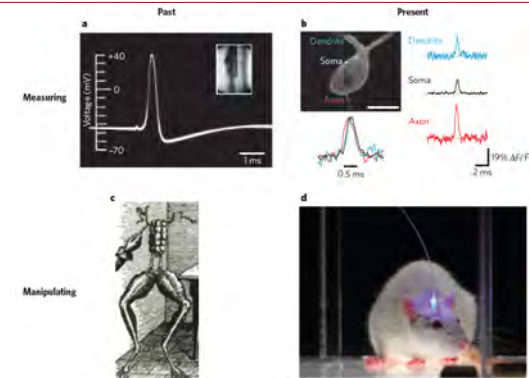

**figure.** mechanotransduction in hair cells of the inner ear. **A.** scanning electron micrograph of hair bundle. this top view shows the stereocilia arranged in order of increasing height. **B.** model for mechanotransduction. deflection of a hair cell's bundle causes the stereocilia to bend and the tip links between them to tighten. **C.** ion channels attached to intracellular elastic elements open in response to tension on the rather inextensible tip link.

[theoretical and computational biophysics group @UUC]

## 6.3 electrophysiology

37

## ion channels - light gated

**figure 1** recording and stimulation: past and present. **a** first action potential recorded intracellularly from a neuron inset, the electrode inserted into a giant squid axon [hodgkin, huxley 1939] **b** multisite optical recording of action potentials in a cerebellar purkinje neuron by using voltagesensitive dyes. **c** electrical stimulation of frog nerve [galvani 1791]. **d** optical deep-brain stimulation of neurons expressing microbial opsin genes [deisseroth lab, stanford]

## 6.3 electrophysiology

38

## ion channels - light gated

[deisseroth lab, stanford]

## 6.3 electrophysiology

39

## active transport - ion pumps

**active** transport requires extra energy in the form of ATP. it is directed **against concentration gradients**, from low to high.

**Figure 6.6:** Active transport through cell membrane containing sodium/potassium pump. The  $\text{Na}^+/\text{K}^+$  pump is the most important ion pump that consumes up to one third of the total energy requirement of a typical animal cell to actively pump cells against concentration gradients.

- example sodium potassium pump
- requires about 1/3 of all the energy of a typical animal cell

## 6.3 electrophysiology

40

## membrane potential

**phase I electrically neutral state**  
initially, both reservoirs contain the same ions, but at different concentrations. both sides are electrically neutral. each + ion is balanced with a - ion on each side of the membrane.

## 6.3 electrophysiology

41

## membrane potential

**phase II selective permeability**  
now the membrane is made permeable to sodium but not to chloride. concentration difference initiates passive transport of  $\text{Na}^+$  along concentration gradients while  $\text{Cl}^-$  distribution remains unchanged.

## 6.3 electrophysiology

42

## membrane potential

**phase III resting state** an equilibrium state is reached when concentration-gradient driven diffusion is balanced by membrane-potential driven forces that keep ions from diffusing

## 6.3 electrophysiology

43

## electric circuit model

Here,  $C_m = c_m A$  where  $c_m$  is the capacitance per area measured in farad per meter squared, i.e.,  $[c_m] = [\text{F} / \text{m}^2]$ . The capacitance of the cell membrane is typically of the order of  $0.01 - 0.1 \text{ F} / \text{m}^2$ . Remember that one farad  $\text{F}$  is defined as the amount of capacitance for which a potential difference of one volt  $\text{V}$  results in a static charge of one coulomb  $\text{C}$ , i.e.,  $[\text{F}] = [\text{C}] / [\text{V}]$  and one coulomb  $\text{C}$  corresponds to  $6.24 \cdot 10^{18}$  ions of elementary charge. Moreover,  $A$  is the membrane surface area,  $\phi$  is the membrane potential, and  $I_{\text{ion}}$  is the ionic current. The most challenging task is to determine a good model for the ionic currents  $I_{\text{ion}}$  and we will address this issue later in this chapter.

kateriya, fuhrmann, hegemann [2001]

6.3 the success story of optogenetics

light opens channelrhodopsin to sodium

nagel, ollig, fuhrmann, kateriya, musti, bamberg, hegemann [2002], berthold, ollig, hegemann, bamberg [2003]

6.3 the success story of optogenetics

photoisomerization of retinal

hegemann, gartner, uhl [1991], lawson, zacks, derguini, nakanishi, spudich [1991]

6.3 the success story of optogenetics 49

delivery via lentiviral vector

boyden, zhang, bamberg, nagel, deisseroth [2005], zhang, wang, boyden, deisseroth [2006], zhang, wang, brauner, liewald, kay, watzke, wood, bamberg, nagel, gottschalk, deisseroth [2007]

6.3 the success story of optogenetics 50

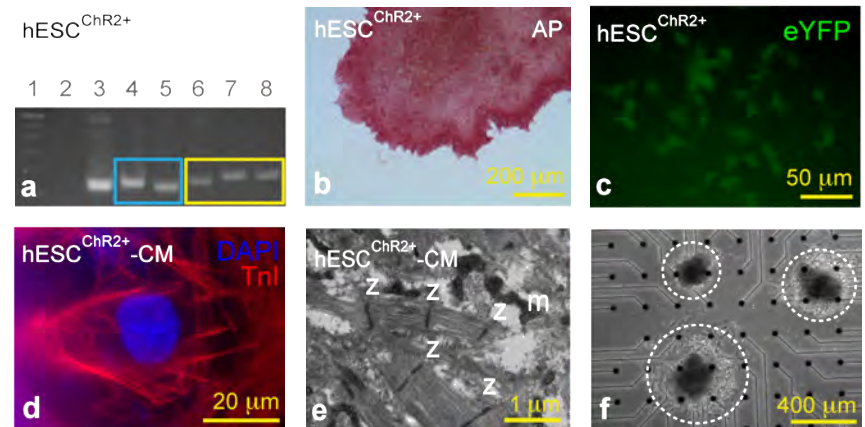

controlling the brain of a mouse

boyden, zhang, bamberg, nagel, deisseroth [2005], deisseroth [2011]

6.3 the success story of optogenetics 51

transduction · division · differentiation

abilez, wong, prakash, deisseroth, zarins, kuhl [2011]

6.3 optogenetics meets the heart 52

## optogenetics across the scales

abilez, wong, prakash, deisseroth, zarins, kuhl [2011]

## 6.3 optogenetics meets the heart

53

## channelrhodopsin photocurrent $I_{ChR2}$

- whole cell voltage patch clamp
- light on: rapid increase, peak, decay, plateau
- light off: rapid drop, decay to zero
- photocurrent increases with light intensity

## 6.3 optogenetics meets the heart

54

## channelrhodopsin photocurrent $I_{ChR2}$

### mathematical model of channelrhodopsin photocurrent $I_{ChR2}$

- photocurrent  $I_{ChR2} = C_{ChR2} g_{ChR2} [\phi - \phi_{ChR2}]$
- conductance  $C_{ChR2} = I_{ChR2}^{\infty} / [g_{ChR2}^{\infty} [\phi_{clamp} - \phi_{ChR2}]]$
- reversal potential  $\phi_{ChR2} = \phi_{Na} - \tilde{\phi}_{Na}$

## 6.3 optogenetics meets the heart

55

## transmembrane potential $\phi$

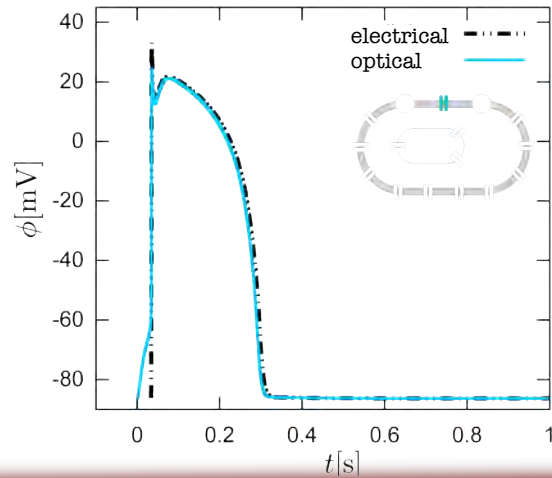

### mathematical model of transmembrane potential $\phi$

$$\dot{\phi} = -\frac{1}{C} [ I_{Na} + I_{bNa} + I_{NaK} + I_{NaCa} + I_{K1} + I_{Kr} + I_{Ks} + I_{PK} + I_{t0} + I_{CaL} + I_{bCa} + I_{PCa} + I_{ChR2} ]$$

## 6.3 optogenetics meets the heart
